CREATIS

Context: The Virtual Imaging Platform

- A science gateway for medical imaging
 - >20 applications
 - >1,000 registered users
- Supported by the **BioMed VO** within EGI
 - 130 computing clusters
 - 65 sites worldwide
 - 50 different Storage Elements (SEs)

Typical execution model in VIP

- Computation distributed across multiple sites
- Numerous SEs used to transfer files
- Focus on file transfers for applications

File replication

Consists in copying the **same file** onto **multiple** SEs.

- Avoid **single-point** failures \rightsquigarrow **higher** availability
- Distribute **network traffic** \rightsquigarrow **shorter** transfer duration

2 aspects:

- Replica creation: **where** and **how many times** to replicate a file
- Replica selection: how to choose the **"best"** replica

File management on EGI

- **APIs** to upload, replicate, and register files
- Replica selection according to the **geographical distance**
- Decisions about **replica creation** are **left to** applications
 - e.g., in VIP, files replicated on 3-5 stable SEs from a predefined list

Why do we need simulation?

- Hardly to evaluate the impact of file replication directly in production
 - time-consuming, non-repeatable, harm production...

From real system to simulation

Reliability of simulation can be improved by feeding **real information**

- Platform model
- Instantiation of parameters

From simulation to real system

Real system can be optimized by **reliable feedback** from simulation

- Test different replication strategies
- Full-scale evaluation

Why do we insist on "realistic"?

Limitation of simulation studies in literature

- **Validation**: questionable applicability to **real systems**
- The most used **metric** is file transfer **durations**
 - But, platform models are often **oversimplified**

Our proposal

- Design a platform model built from real **execution traces**
- **Parameter injection** in simulation scenarios
- **Cross-evaluation** with the state-of-the-art model

Questions to answer

- What is the impact of replication strategies on file transfer **duration**?
- Does the impact change on different **platform models**?
- What would be **reliable** recommendations for file management in VIP?

- 1 Introduction
- 2 Replication strategies and platform models**
- 3 Simulation evaluation
- 4 Conclusion and future work

Replication strategies

Static replication

- Decisions made before application starts and **invariant** during the execution of application
- How to choose SEs to have the **best combination**?
 - one combination of SEs = one prestaging list
- Random vs. based on statistical information on **where** jobs were executed

Observations

- a given site executes more than one job
- large variable queuing time on EGI

Dynamic method

Dynamic replication

- Decisions adapted to **changes** of the system during the execution of application
- Our proposal : a practical method inspired from "**cache hit**"
- The first job in a site replicates the downloaded file onto its **local SE**

- 3-level hierarchical model
 - A **widely used** model in literature
 - 3-level **network hierarchy**: local, national, and inter-country
 - **Unique theoretical** bandwidth for each link category
 - Proposal: Enhance by **average bandwidth** derived from traces
 - local: 1.3 Gb/s, national: 255Mb/s, and inter-country: 100 Mb/s
 - **Pros**: **Simplicity** to build a **complete** network model
 - **Cons**: Hardly capture the **heterogeneity** of EGI
- Trace-based model
 - **Derive** network bandwidth from **measured transfer durations**
 - **Spatial aggregation** of multiple traces
 - **Pros**: **Reproduce** real-life **variability**
 - **Cons**: Construction **complexity** and **missing** links
 - Proposal: Fill missing links by leveraging **existing information**

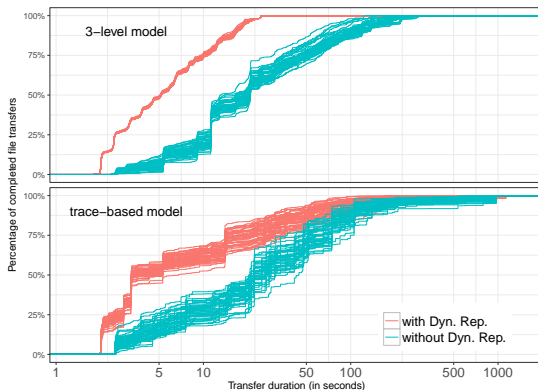

- 1 Introduction
- 2 Replication strategies and platform models
- 3 Simulation evaluation**
- 4 Conclusion and future work

Simulation of file transfers

- **Realistic** information extracted from execution **logs**
 - 15 **execution** instances of the typical workflow
 - Each one consists of 100 **jobs**
 - The **queuing time** and **execution site** of jobs (**injected** in simulation)
- **Prestaging list** = 3 SEs (among 32 SEs) for static replica creation
- 55 different prestaging lists
 - Current **production setting**: 3 SEs in France
 - Without a priori information: 50 **random** lists of 3 SEs
 - With a priori information: 4 lists based on the **job distribution**
- 220(2*2*55) scenarios for each workflow
↪ 330,000 (220*15*100) simulated file transfers

Q1: Impact of dynamic replication

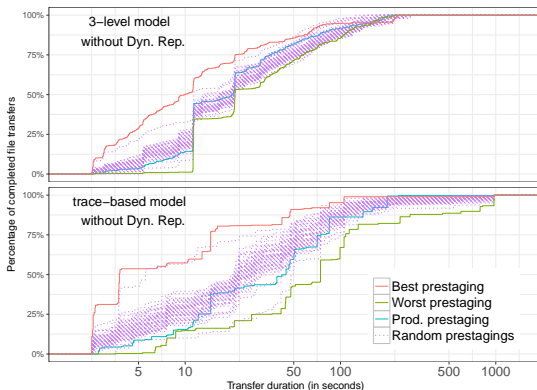

- 50 random lists of 3 SEs for both models

- Dynamic replication **decreases** transfer durations for both models
 - Larger improvement in 3-level model
- **Prestaging** lists have stronger impact without dynamic replication

Q1: Impact of different prestaging lists

- 50 random lists + 4 predefined list + the current production setting

- Best prestaging list is the same for both models
- SE list for best prestaging \rightsquigarrow sites with most jobs in 3 countries
 - Replicate close to jobs and scatter in different countries

Q2: Impact of platform model

With Dynamic Replication

- 3-level: random prestaging is enough
- TB model: large performance variability depending on the SEs

Without Dynamic Replication

- With a-priori information, the best predefined list > the best random list
- Improvement is larger in TB model

- More heterogeneity in the platform \rightsquigarrow more gain comes from a-priori knowledge

Q3: Recommendations for file replication in VIP on EGI

- Without Dynamic Replication:
 - Replicate files **close** to the sites executing most jobs
 - **Scatter** across different countries
 - **Best results** are **comparable** to dynamic replication
 - requires to estimate **where jobs will be executed**
- With Dynamic Replication:
 - **Always better** than **Prod.prestaging**
 - **Reliable** method to reduce the file transfer durations

- 1 Introduction
- 2 Replication strategies and platform models
- 3 Simulation evaluation
- 4 Conclusion and future work**

Take-home messages

Realistic simulation

- Different platform models \rightsquigarrow **different qualitative** assessment
- **Realism** of the platform model is **key** to the evaluation process
 - And also to the applicability for production systems

Recommendations for file management on EGI

- Replicate data **close to jobs**
 - Requires **a-priori** information
 - Further optimization by **dynamic replication**
 - **Non-negligible** implementation cost
 - **Scatter across countries** is a **safe** strategy
 - **A-priori** information is very important for a **heterogeneous** platform
-
- Still **lots of aspects** to investigate

- Study the impact of **the number** of prestaging SEs
- Further improve the **accuracy** of trace-based model
 - Integrate **temporal aggregation** of traces
 - Investigate **different methods** to fill missing links
- Consider other parameters in simulation scenarios
 - Transfer **failure rates**
 - Available **storage space**
- Build **probability distributions** out of traces for these parameters

Hypothesis

- For a site S_i , the **connectivity** to SEs follows the **network hierarchy**
- **Measured links** to/from S_i could reflect its **general** connectivity
- **Reliability** depends on the **number** of known links

$$C_i = \sum_c \left(\frac{|L_i^c|}{|L_i|} \cdot \frac{\widetilde{B}_i^c}{\widetilde{B}^c} \right) \quad (1)$$

- Bandwidth of a **missing link** of category c **to/from** S_i : $\widetilde{B}^c \times C_i$
- Category c : local, national, and inter-country
- \widetilde{B}^c : median bandwidth of **all known links** in category c
- \widetilde{B}_i^c : median bandwidth of the known links **to/from** S_i in category c
- $|L_i|$: the **total number** of known links for site S_i
- $|L_i^c|$: the number of known links **to/from** S_i in category c

4 predefined prestaging list of 3 SEs

- SEs of the top 3 sites with most executed jobs in one country
- SEs of sites with the most executed jobs in 3 country
- SEs of 3 sites with no executed jobs in one country
- SEs of sites with no executed jobs in 3 country

Replica selection on EGI

- First, the local SE of the computing site
- Then, the SE in the same country as the job execution
- Randomly among all available replicas
